

INFO 6205 Program Structures & Algorithms [Fall 2021]

Assignment 1 (Random Walk)

1. Your conclusion about the relationship between d and n

$D = \sqrt{n}$ particularly when $n \rightarrow \infty$.

2. Your evidence to support that relationship

The result can be seen as:

```

public static void main(String[] args) {
    if (args.length == 0)
        throw new RuntimeException("Syntax: RandomWalk steps [experiments]");
    int m = Integer.parseInt(args[0]);
    int[] m = new int[10];
    int n = 5000;

    for (int i = 0; i < 10; i++) {
        // Recycle the same function.
        m[i] = (i+1)*(i+1);
    }

    if (args.length > 1) n = Integer.parseInt(args[1]);
    for (int j:m) {
        double meanDistance = randomWalkMulti(j, n);
        System.out.println(j + " steps: " + meanDistance + " over " + n + " experiments");
    }
}

```

```

"C:\Program Files\Amazon Corretto\jdk11.0.12_7\bin\java.exe" ...
1 steps: 1.0 over 5000 experiments
4 steps: 1.7552597162736119 over 5000 experiments
9 steps: 2.681328678247449 over 5000 experiments
16 steps: 3.449671523486903 over 5000 experiments
25 steps: 4.446499363957987 over 5000 experiments
36 steps: 5.338807094210894 over 5000 experiments
49 steps: 6.219624050048926 over 5000 experiments
64 steps: 7.1547961536278715 over 5000 experiments
81 steps: 7.915282648833728 over 5000 experiments
100 steps: 8.858747559884126 over 5000 experiments

Process finished with exit code 0

```

When it comes to the random walk question, per the statement, the man has the ability to walk with a unit length of 1 in a 2-Dimensional space. (Unless he can fly with a rocket launcher I reckon?) Therefore, the distance D shall consists of horizontal (Let's say, from the west to the east in this case.) component, plus the vertical (Evidently, it would be from the south to the north in this case.) component. We denote that x_i represents the length of the horizontal component, and y_i represents the vertical component. Therefore, the distance D can be expressed as:

$$D = \sqrt{(\sum_{i=1}^n x_i)^2 + (\sum_{i=1}^n y_i)^2} \quad \text{whereas } x_i \text{ and } y_i \text{ are } \pm 1 \text{ since they are directional.}$$

Since my math skill sucks, please allow me to start focusing on one dimension at first, the horizontal, or from the west to the east you may say.

Let us denote the total of the horizontal component to be D_x , then we will have:

$$D_x = \sum_{i=1}^n x_i = x_1 + x_2 + \dots + x_n$$

If we say that there is 50 – 50 chance for the man to walk + 1 or – 1, then it makes no sense to claim that when $n \rightarrow \infty$, the average would go to 0, which sounds like bullshit. However, do note that we are in a 2-Dimensional system, and we are trying to track how far the man has go from the origin location to the end point. Hence, we have to factor in the direction. Since D_x can be positive or negative depending on the direction. In order to rule out the influence of direction, to some extent, we need to compute D_x^2 instead, since it is always going to be positive.

In this way, we can get the expression of D_x^2 as:

$$\begin{aligned}
 D_x^2 &= \left(\sum_{i=1}^n x_i \right)^2 = (x_1 + x_2 + \dots + x_n)^2 \\
 &= [(x_1)^2 + (x_2)^2 + \dots + (x_n)^2] + 2 \times [(x_1x_2 + x_1x_3 + \dots + x_1x_n) + \\
 &\quad (x_2x_3 + x_2x_4 + \dots + x_2x_n) + \dots + (x_{n-1}x_n)]
 \end{aligned}$$

Let us consider x_i , since each value is either $+1$ or -1 , therefore, it is evident that x_i^2 is simply 1. However, when it comes to the latter part of the expanded portion in the aforementioned expression, we can get a table to illustrate the possible outcomes of $x_i x_j$ whereas $i \in [1, n], j \in [i, n]$ whereas both i and j are integers.

x_i	x_j	$x_i x_j$
1	1	1
-1	1	-1
1	-1	-1
-1	-1	1

According to the table, we can see that $x_i x_j$ have 50 – 50 chance to be either $+1$ or -1 . Then, we can conclude that when $n \rightarrow \infty$, the sum of all $\sum_{i=1}^n \sum_{j=i}^n x_i x_j$ would be 0. Hence, the previous expression of D_x^2 can be estimated as:

$$D_x^2 = [1 + 1 + \dots + 1] + 2 \times 0 = n$$

Similarly, if we look at the vertical direction, or from the south to the north in this case scenario, we will be able to yield:

$$D_y^2 = [1 + 1 + \dots + 1] + 2 \times 0 = n$$

The last step is to put them together to compute the square of the overall distance D , which can be expressed as D^2 . Since there is 50 – 50 chance for the man to walk either in horizontal or vertical direction. $P_x = \frac{1}{2}$ and $P_y = \frac{1}{2}$

$$D^2 = P_x D_x^2 + P_y D_y^2 = \frac{1}{2} \times n + \frac{1}{2} \times n = n$$

To simply put, the expression of D can be expressed as:

$$D = \sqrt{n} \text{ particularly when } n \rightarrow \infty.$$

3. Your code (RandomWalk.java plus anything else that you changed or created)

In `RandomWalk.java` :

The following code is added:

```
/**
 * Private method to move the current position, that's to say the drunkard moves
 *
 * @param dx the distance he moves in the x direction
 * @param dy the distance he moves in the y direction
 */
private void move(int dx, int dy) {
    // TO BE IMPLEMENTED
    // First, we need to know that x is the accumulation of dx.
    // And y is just the accumulation of dy

    x += dx;
    y += dy;

    // I think that should be it?
}
```

```
/**
 * Perform a random walk of m steps
 *
 * @param m the number of steps the drunkard takes
 */
private void randomWalk(int m) {
    // TO BE IMPLEMENTED
    // So we will have m iterations.
    for (int i = 0; i < m; i++){
        // Then we call out the randomMove I reckon?
        // Otherwise it is gonna be a clusterfuck.
        randomMove();
    }
}
```

```
/**
 * Method to compute the distance from the origin (the lamp-post where the drunkard starts) to his current position.
 *
```

```

    * @return the (Euclidean) distance from the origin to the current position.
    */
    public double distance() {
        // TO BE IMPLEMENTED

        // Now we calculate the thing as:
        double dist_temp = Math.sqrt(Math.pow(x, 2) + Math.pow(y, 2));

        //return 0;
        // Instead of returning 0.
        return dist_temp;
    }
}

```

This code is used to generate the relationship table for [Section 2](#) .

```

    public static void main(String[] args) {
        //      if (args.length == 0)
        //          throw new RuntimeException("Syntax: RandomWalk steps [experiments]");
        //      int m = Integer.parseInt(args[0]);
        int[] m = new int[10];
        int n = 5000;

        for (int i = 0; i < 10; i++) {
            // Recycle the same function.
            m[i] = (i+1)*(i+1);
        }

        //      if (args.length > 1) n = Integer.parseInt(args[1]);
        for (int j:m) {
            double meanDistance = randomWalkMulti(j, n);
            System.out.println(j + " steps: " + meanDistance + " over " + n + " experiments");
        }
    }
}

```

4. A screen shot of the unit tests all passing

The screenshot displays an IDE with the following components:

- Project Explorer:** A tree view on the left showing a project structure with various folders like 'codelength', 'coupling', 'dynamicProgramming.coir', 'equable', 'functions', 'graphs', 'greedy', 'hashtable', 'lab_1', 'life', 'pq', 'randomwalk', 'reduction', 'runLengthEncoding', 'sort', 'symbolTable', 'threesum', 'union_find', 'util', and 'BinarySearch'.
- Code Editor:** The main area showing the source code for `RandomWalkTest`. It includes two test methods:
 - `testMove0()`: Tests the distance after 0 moves, expecting 1.0.
 - `testMove1()`: Tests the distance after 1 move, expecting 1.0.
- Run Console:** A window at the bottom showing the execution results. It indicates that all 6 tests passed successfully, with a total time of 79 ms. The tests listed are:
 - `testRandomWalk2` (5 ms)
 - `testMove0` (1 ms)
 - `testMove1` (0 ms)
 - `testMove2` (1 ms)
 - `testMove3` (1 ms)
 - `testRandomWalk` (71 ms)
